This mini-unit covers density, including the overall density meaning of some experiments and problems Give your students the practice of determining mass and volume density through different idea problems with responses at the end of the package to help students check their responses. Students will calculate density to identify unknown materials. They will be given some information. Then students will find the mass of each liquid and use the information to calculate the density or volume according to the problem This spreadsheet is designed to help students understand the relationship between mass, volume and density. Very often students have difficulty understanding the relationship between the three variables when the numbers are in the question. This spreadsheet helps them understand their density without using the numbers. Students will be very committed to this spreadsheet of worksheet problems with Density Calculations Worksheet Answer Key responses: you can also open it in the document window and start customizing it immediately if you find a template that you want to use. At this time we are delighted to declare that we have discovered a very interesting topic to review. Some people looking for information about the density worksheet response key and definitely one of them is you, isn't it? Practical Density Problem Worksheet Responses density key worksheet response calculations, source: mychaume.com Density calculations Spreadsheet and calculations key spreadsheet response, source: studylib.net Chemistry Problems of new density practice Problems of the density key calculations of spreadsheet response, source: transatlantica-news.com Jump to: Rock and mineral density | Specific gravity of rock and mineral You can download the questions (Acrobat (PDF) 25kB Jul24 09) if you want to work them on a separate sheet of paper. Problem 1: You have a rock with a volume of 15cm³ and a mass of 45 g. What is its density? The concealment density is divided en masse by volume, so the density is 45 g divided by 15cm³, which is 3.0 g/cm³. Problem 2: You have a different rock with a volume of 30cm³ and a mass of 60g. What is its density? The concealment density is divided en masse by volume, so the density is 60 g divided by 30cm³, which is 2.0 g/cm³. Problem 3: In the two examples above which rock is heavier? What is lighter? Hiding the question is to ask about heavier and lighter, which refers to mass or weight. Therefore, all you care about is the mass in grams and therefore the rock of 60 g in the second problem is heavier and the rock of 45 g (in the first question) is lighter. Problem 4: In the two examples above which rock is denser? which is less dense? Hiding the question is asked about density, and this is the ratio of mass to Therefore, the first rock is denser (density = 3.0) and the second rock is less dense even though it weighs more, because its density is only 2.0. This example shows why it is important to be careful not to use the heavier/lighter words when it means more or less dense. Problem 5: You decide to bring a rock house from the beach. It is 30 centimeters on each side, and also has a volume of 27,000 cm³. It is made of granite, with a typical density of 2.8 g/cm³. How much will this boulder weigh? Hide in this case, you are asked for a mass, not density. You will need to reorganize the density equation for you to get too much. When multiplying both sides by volume, the dough is left alone. Replacing the problem values, the result is that the dough is 75,600 grams. That's over 165 pounds! Hide Problem 6: Rocks are sometimes used along the coasts to prevent erosion. If a rock has to weigh 2,000 kilograms (about 2 tons) not to be displaced by the waves, how big (what volume) should it be? You are using basalt, which has a typical density of 3200 kg/m³ Hide In this problem you need a volume, so you need to rearrange the density equation to get volume. By multiplying both sides by volume, we can get numerator volume (the bottom). Then you can split both sides by density to get volume alone: Replacing the values listed above, the volume will be 0.625 m³ Note that the above problem shows that the densities may be in units other than grams and cubic centimeters. To avoid the possible problems of the different units, many geologists use specific gravity (SG), explored in problems 8 and 9, below. Hide the image ifischer/Collections/Fossils/rocks.html problem 7: A golden cube is delivered to you. The person wants you to buy it for \$100, saying it's a gold seed. Remove the text from ancient geology and look for gold on the mineral table, and read that its density is 19.3 g/cm³. The cube is measured and found to be 2 cm on each side, and weighs 40 g. What is its density? Is it gold? Should you buy it? Hide to determine the density needed by volume and mass from . You know the dough (40 g), but the volume is not given. To find the volume, use the formula for the volume of a box volume = length x width x height. The cube volume is 2cm x 2cm x 2cm = 8cm³. The density then is the mass divided by volume: Therefore, the cube is not gold, since the density (5.0 g/cm³) is not the same as gold (19.3g/cm³). You tell the seller to take a walk. You might even notice that the pirt density (also a.k.a. gold of the fool) is 5.0 g/cm³. Fortunately you're not silly and you know about density! Density!
